

“Structure and Dynamics of Trust in Anonymous and Identified Online Networks”

Complex Network Dynamics, CS-484
Project Presentation, Phase A
Papadakis Georgios (4975)
Supervisor: Dr. Lionakis Panagiotis

Problem Definition and Motivation

- **Central Question:** *How does anonymity affect the structure, stability and diffusion of trust in online signed networks?*
- **Κίνητρο:** Many platforms operate under anonymity. To ensure stability within the network they are forced to develop reputation mechanisms that are not based on external user identities.
- **Hypotheses:**
 - **Polarization:** The anonymous network will have more extreme ratings.
 - **Fragility:** Trust will be concentrated in a few nodes (Hubs).
 - **Structural Balance:** Fewer balanced triangles due to lack of social pressure.

Dataset Overview

- **Bitcoin OTC (Anonymous)**
 - **Source:** P2P trading platform.
 - **Scale:** -10 (for distrust) to +10 (for trust).
 - **Goal:** Protection against fraud.
 - **Key Statistics:**
 - 5.881 nodes
 - 35.592 edges
- **Epinions (Pseudo-Identified)**
 - **Source:** Consumer review site.
 - **Scale:** -1 (for distrust) or +1 (for trust).
 - **Goal:** Web of Trust for filtering reviews.
 - **Key Statistics:**
 - 131.828 nodes (x22 BTC)
 - 841.372 edges (x23 BTC)

Both networks are directed and signed.

First Findings (1)

- **Cleaning Process:** Remove NaN, Self-Loops, Duplicates
 - **After Cleaning:**
 - 131.580 nodes (-248) in Epinions and 840.799 edges (-573), due to self-loops
 - 0.001029 density of Bitcoin OTC
 - 0.000049 density of Epinions
 - **Observation:**
 - Bitcoin OTC is **20 times denser** than Epinions.
 - Thus, it is a more “tight-knit” community, despite anonymity.
- Rating Distribution Analysis**
- **Bitcoin OTC:**
 - Positive ≈ 90%, Negative ≈ 10%
 - **Strong Signaling:** Significant percentages at the extremes (-10, +10). Users are “shouting”. (see Hypothesis 1)
 - **Epinions:**
 - Positive ≈ 85%, Negative ≈ 15%

First Findings (2)

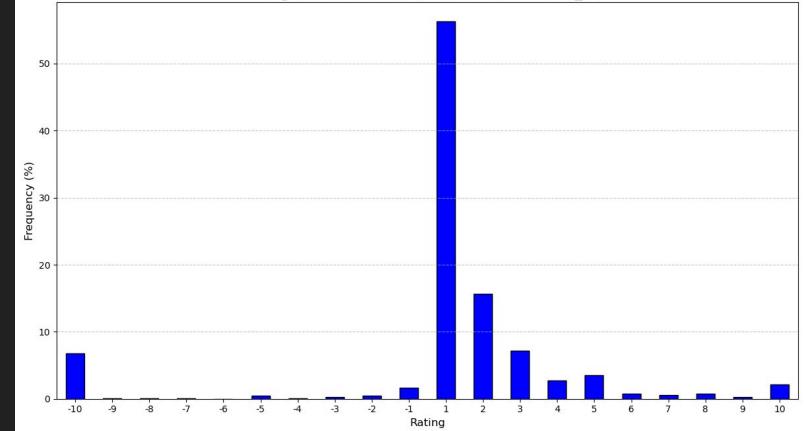

Degree Distribution Analysis

- The majority of nodes have very low In and Out-Degree.
- Few nodes have hundreds of connections, functioning as Hubs.
- The “tail” in Bitcoin OTC drops more steeply compared to Epinions
 - Even if less dense, EPinions has more “active” users.

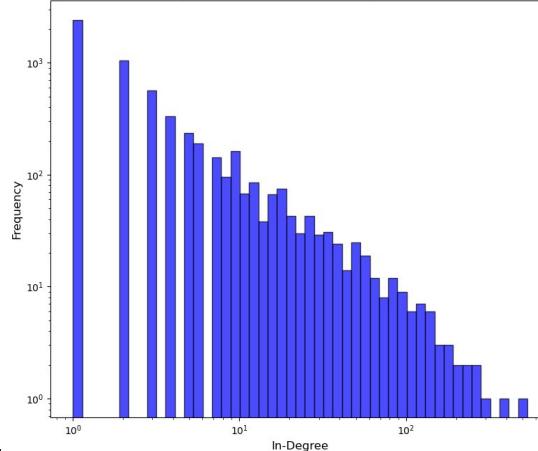

Weighted Degree Distribution Analysis

- The majority of nodes have “reputation” close to zero.
- **Bitcoin OTC:** In [-750, 1.000], Out [-1.000, 800]
- **Bitcoin OTC (Normalized):** In [-100, 600], Out [-100, 800]
- **Epinions:** In [-600, 3.000], Out [-1.500, 2.000]

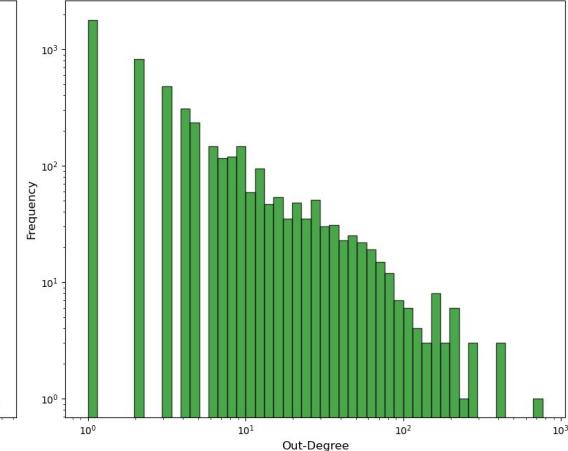

Rating (Trust/Distrust) Distribution for Bitcoin_OTC

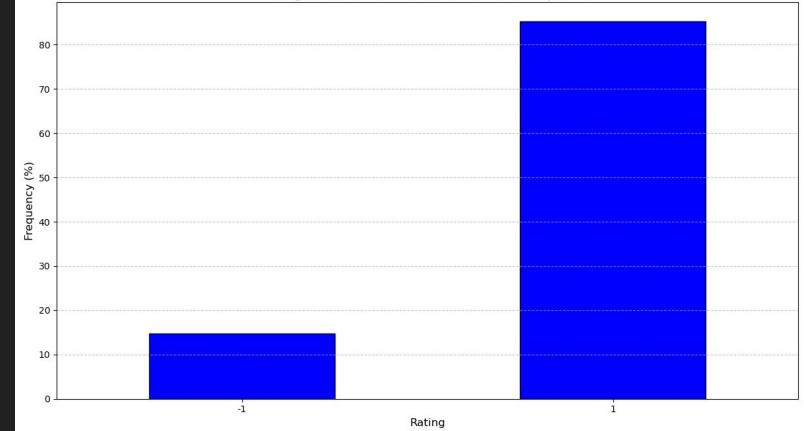

In-Degree Distribution for Bitcoin_OTC (Log-Log)

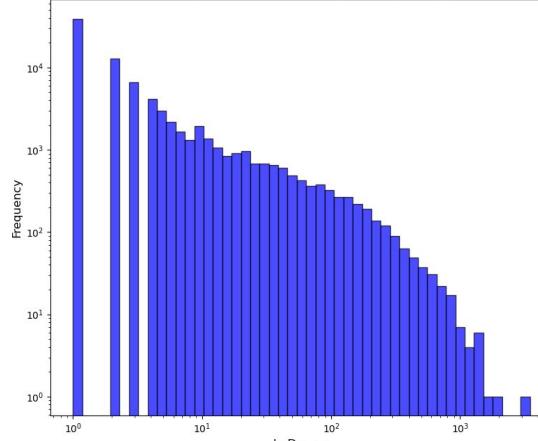

Out-Degree Distribution for Bitcoin_OTC (Log-Log)

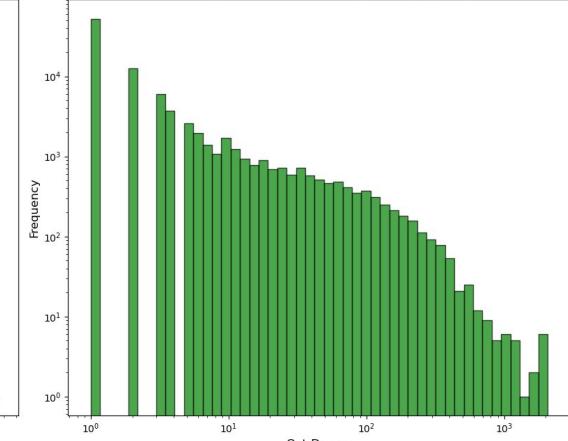

Rating (Trust/Distrust) Distribution for Epinions

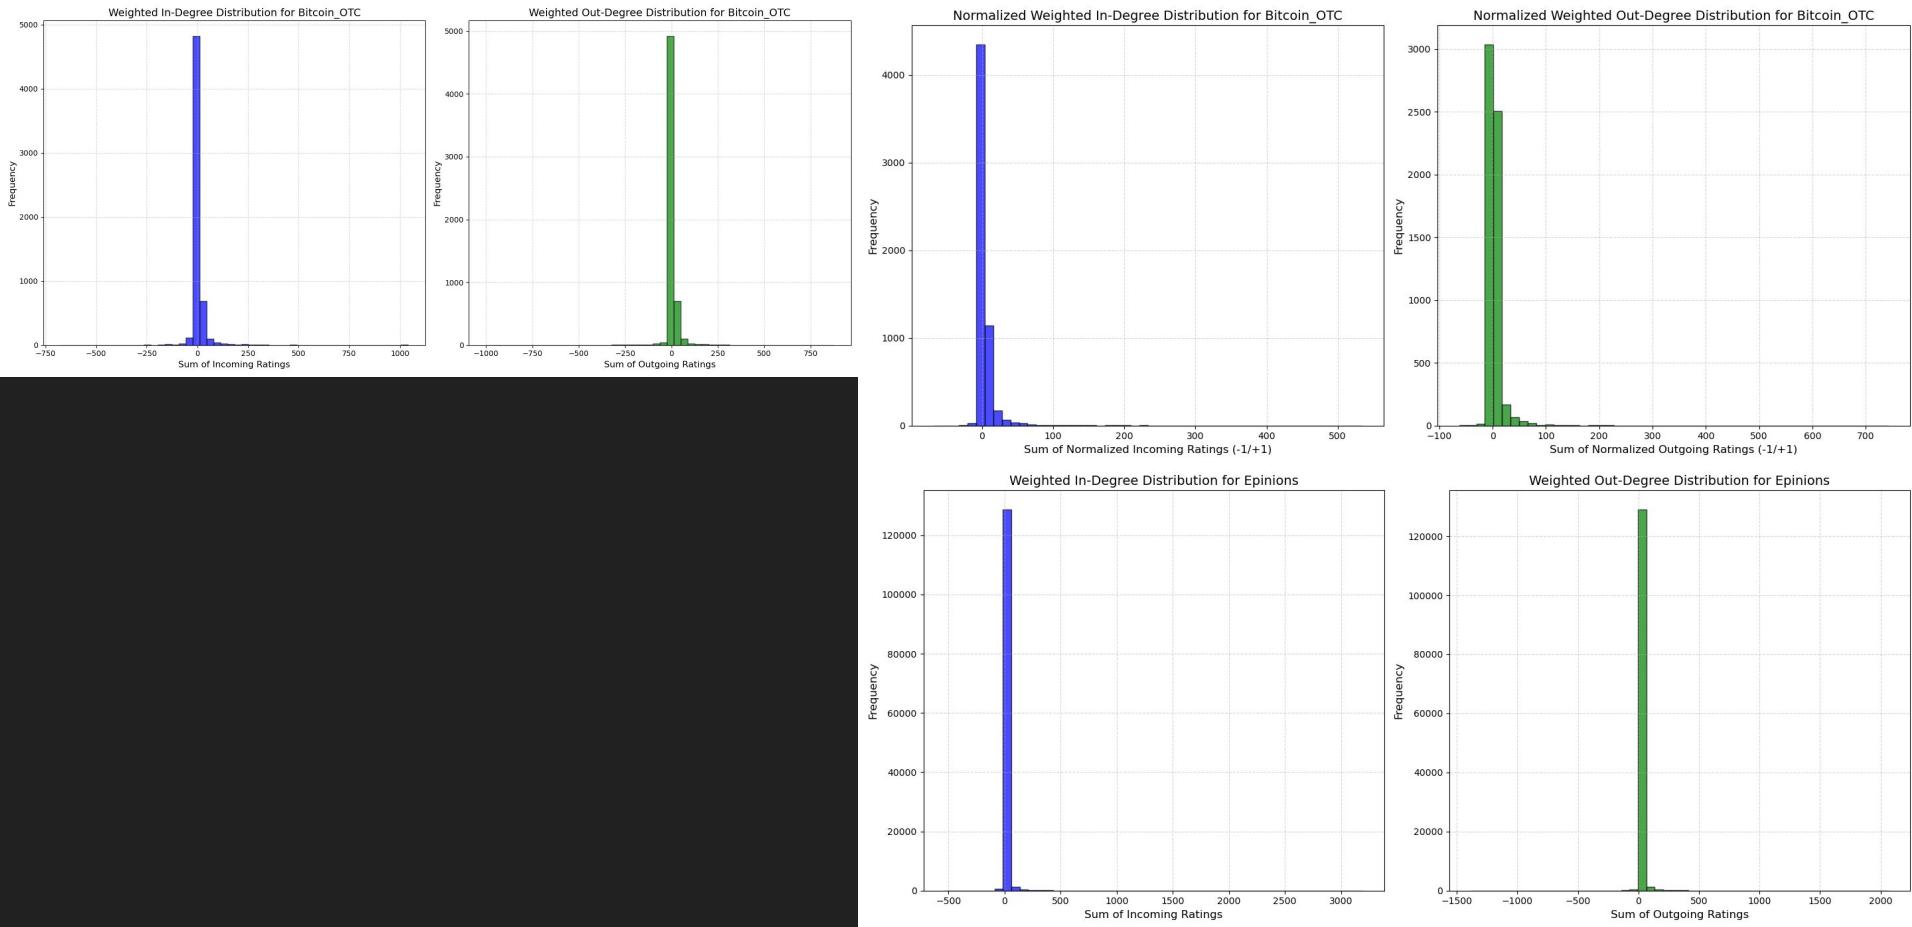

In-Degree Distribution for Epinions (Log-Log)

Out-Degree Distribution for Epinions (Log-Log)

Next Steps and Expected Outcomes

- **Analysis On:**
 - Power Law
 - Clustering Coefficient
 - Average Path Length
 - Reciprocity (Mutuality)
 - PageRank & Eigenvector Centrality
 - Trust Transitivity (if trustworthiness is “contagious”)
 - Structural Balance
 - Robustness Analysis
- **Σύγκριση Ευρημάτων**
- **Συγγραφή Τελικής Αναφοράς και Παρουσίασης**
- I expect to show that anonymity makes networks:
 - more fragile,
 - less structurally balanced,
 - have more polarized rating patterns.
